Bed Bug Facts

Lay from one to twelve eggs per day. Eggs are deposited on rough surfaces or in crack and crevices. Eggs are coated with a sticky substance so they adhere to the substrate. Eggs hatch 6 to 17 days. Nymphs can immediately begin to feed. They require a blood meal in order to molt. Developmental time (egg to adult) is affected by temperature and takes about 21 days at 86° F to 120 days at 65° F. The nymphal period is greatly prolonged when food is scarce. Nymphs and adults can live for several months without food. The adult's lifespan may encompass 12-18 months. Three or more generations can occur each year.

Bed bugs hide in dark, protected sites. Tufts, seams, and folds of mattresses, window and door frames, electrical boxes, floor cracks, baseboards, furniture, and under the tack board of wall-to-wall carpeting. pictures, wall hangings, drapery pleats, loosened wallpaper, cracks in plaster, and ceiling moldings. Anywhere is possible!

Sanitation measures include frequently vacuuming the mattress and premises, laundering bedding and clothing in hot water, and cleaning and sanitizing dwellings. After vacuuming, immediately place the vacuum cleaner bag in a plastic bag, seal tightly, and discard in a container outdoors-this prevents captured bed bugs from escaping into the home. A stiff brush can be used to scrub the mattress seams to dislodge bed bugs and eggs. Discarding the mattress is another option, although a new mattress can quickly become infested if bed bugs are still on the premises. Steam cleaning of mattresses generally is not recommended because it is difficult to get rid of excess moisture, which can lead to problems with mold, mildew, house dust mites, etc.

Repair cracks in plaster and glue down loosened wallpaper to eliminate bed bug harborage sites.
